

■ TITLE: "DON'T KILL Your PC! Power Supply Blunders to AVOID !!!"

Casual Creator-Style Script for VGT

----- ■ INTRO (0:00 – 0:30)

"Guys... please — don't kill your PC! You might've spent thousands on your CPU, GPU, RAM... but if your power supply is garbage — it can take everything down with it ■ Today, I'll show you the biggest PSU mistakes that can literally destroy your PC — and how to avoid them. Let's go!"

----- ■■ 1. Underrated Power Supply (0:30 – 1:15)

"First up — underrated PSUs. I see people running RTX 4080s on 500W PSUs like it's nothing. Sure, your PC boots... but the moment you start gaming — it'll crash, throttle, or worse. Always use a PSU calculator and add 25–30% extra wattage headroom. And go for at least 80+ Gold efficiency — no compromises."

■ Tip: Aim for 30% headroom | 80+ Gold or better

----- ■ 2. Cheap or Unknown Brands (1:15 – 2:00)

"Number two — don't cheap out! That ■1500 PSU claiming 750W peak? Yeah, that's a ticking bomb. These knock-offs lie about wattage, have no surge protection, and can fry your GPU, motherboard — even your SSD. Stick to reputed brands like Corsair, MSI, Seasonic, Cooler Master — you'll thank yourself later."

■ Avoid: Generic / Unknown PSUs ■ Use: Corsair | Seasonic | MSI | Cooler Master

----- ■■ 3. Mixing or Reusing PSU Cables (2:00 – 2:45)

"Big mistake number three — mixing PSU cables. I know all those modular cables look the same — but they're not universal! Plugging a cable from another PSU can short your motherboard instantly. Always — and I mean always — use the cables that came with your PSU."

■■ Warning: Never mix modular PSU cables — even same brand!

----- ■ 4. Bad PSU Placement or Airflow (2:45 – 3:30)

"Alright, next — airflow and orientation. If your PSU fan is facing up against your GPU or resting on carpet — that's bad news. It's sucking hot air or dust, and that kills lifespan fast. Mount it fan-down if your case has a vent, or make sure there's proper clearance."

■ Tip: Keep airflow clean | Avoid dust intake

----- ■ 5. Overloading One Cable (3:30 – 4:15)

"Number five — don't overload a single cable. Don't use one PCIe cable with a splitter for two GPU ports — that's a rookie move. Always use separate, dedicated PCIe cables for each power input on your GPU. Trust me, it keeps things cooler and safer."

■ Tip: 1 cable = 1 power connector | No splitters

----- ■ 6. Old or Worn-Out PSU (4:15 – 5:00)

"And finally — using your ancient PSU in a new build. Just because it still turns on doesn't mean it's safe. Capacitors degrade over time, and voltage output becomes unstable. If your PSU is over 5 years old or came from a budget series — just replace it. Don't risk your new GPU."

■ Tip: Replace PSUs every 5 years or after 2 major GPU upgrades

----- ■ OUTRO (5:00 – 5:30)

“Your PSU is literally the heart of your PC. You wouldn’t power a Lamborghini with a bike battery, right? So, respect the power supply! If this helped you out, hit that like button ■, subscribe for more PC build tips, and drop your worst PSU horror story down below ■ This is VGT, and I’ll catch you in the next one!”
